DEVELOPMENT PROCESS

ServiceNow-Based Employee Laptop Request Application

Project Area	Implementation Summary
Platform	ServiceNow custom application and Service Portal
Request entry	Record Producer named “Laptop Request”, added to the Employee Service Catalog
Request data	Custom Laptop Request Form table (u_laptop_request_form) with request, employee, manager, type, status and reason fields
Workflow	Flow Designer starts when a Laptop Request Form record is created; manager approval determines the outcome
Controls	Business Rule prevents a second request by the same requester in the same calendar year; roles, groups and ACLs control access
Completion status	Development is complete. Approval workflow, email notifications, duplicate-request rule and roles/groups/ACLs were confirmed by the developer as working.

1. Development Scope

The application replaces informal laptop requests made through email or verbal communication with a controlled digital request process. Employees submit a standard form, the system records the request, the manager reviews it, and notifications communicate the outcome. The request type distinguishes Basic use from Advanced technical or software-development use.

2. Data Model and Table Configuration

Field	Type / configuration	Purpose
Number	Auto Number	Unique request identifier generated by the system.
Requester	Reference to User table	Identifies the employee submitting the request.
Employee Email	Email	Contact email for the requester.
Request Date	Date/Time	Records when the request was submitted.
Short Description	String	Brief summary of the request.
Manager	Reference to User table	Identifies the manager who reviews the request.
Type of Request	Choice: Basic / Advance	Captures the intended laptop usage type.
Status	Choice: Pending Approval / Approved / Rejected	Tracks the current request outcome.
Reason	Choice: Software Development / Personal Use / Other	Captures the stated reason for the request.

The request number is generated by the system and is not intended to be entered by the employee. The Record Producer variables are mapped to the corresponding fields in the custom table.

3. Record Producer and Service Catalog

Step	Implementation detail
1	Created a Record Producer named “Laptop Request” for the Laptop Request Form (u_laptop_request_form) table.
2	Added the required request variables and aligned their types with the target table fields.

Step	Implementation detail
3	Mapped the Record Producer variables to the table fields so submitted values create the request record.
4	Added the Record Producer to the Employee Service Catalog so employees can submit requests through the Service Portal.

4. Approval Relationship and Flow Designer

Component	Configured behavior
Trigger	When a record is created on Laptop Request Form (u_laptop_request_form).
Approval records	Approval handling is associated with the ServiceNow approval table, sysapproval_approver.
Approver	The manager selected for the request is the intended approver.
Outcome	The request status is updated according to approval or rejection.
Notifications	Email notifications are configured to inform the relevant approver/requester at the appropriate stage.

Developer-confirmed result: the approval workflow and email notifications are working. The separate UAT document records that formal user acceptance testing has not yet been performed.

5. Business Rule: Prevent Duplicate Annual Requests

A server-side Business Rule runs before insertion on the Laptop Request Form table. It checks whether the same requester already has a request within the current calendar year. If a matching request exists, the new insertion is blocked and an explanatory error message is shown. This enforces the project policy of one laptop request per employee per year.

Developer-confirmed result: the duplicate-request rule is working.

6. Roles, Groups and Access Control

Security element	Purpose / configured access
it_employee role	Allows employees to create and access laptop request records as configured for the application.
it_manager role	Provides manager access intended for reviewing request information and approvals.
IT Employees group	Groups employee users and is associated with the employee role.
IT Managers group	Groups manager users and is associated with the manager role.
ACLs	Configured for read, create and write operations to restrict application data access according to role.

Developer-confirmed result: roles, groups and ACLs are working. The exact effective permissions should still be verified during formal UAT using representative employee and manager accounts.

7. Development Verification and Deployment

Area	Development activity / completion
Update Set	Used a dedicated local Update Set to capture application configuration changes.
Configuration capture	Included the custom application, table and fields, Record Producer, Business Rules, ACLs and Flow Designer approval workflow.
Preview and conflict handling	Previewed the Update Set and resolved any conflicts before committing.
Transfer	Exported the completed Update Set as XML for transfer to another ServiceNow instance.
Final development status	Development is complete according to the project owner. Formal UAT remains outstanding.

8. Development Completion Summary

Feature	Development status
Record Producer and request record creation	Configured
Manager approval workflow	Working (developer-confirmed)
Email notifications	Working (developer-confirmed)
Annual duplicate-request prevention	Working (developer-confirmed)
Roles, groups and ACLs	Working (developer-confirmed)
Formal User Acceptance Testing	Not yet performed

Prepared from the project implementation details and the supplied SkillWallet development screenshots. “Working” statuses in this document reflect the developer’s confirmation; they are not presented as results of formal UAT.
